Strings Chapter 6

String Data Type

- A string is a sequence of characters
- A string literal uses quotes 'Hello' or "Hello"
- For strings, + means "concatenate"
- When a string contains numbers, it is still a string
- We can convert numbers in a string into a number using int()

```
>>> str1 = "Hello"
>>> str2 = 'there'
>>> bob = str1 + str2
>>> print bob
Hellothere
>>> str3 = '123'
>>> str3 = str3 + 1
Traceback (most recent call
last): File "<stdin>", line
1, in <module>TypeError:
cannot concatenate 'str' and
'int' objects
>>> x = int(str3) + 1
>>> print x
124
>>>
```

Reading and Converting

- We prefer to read data in using strings and then parse and convert the data as we need
- This gives us more control over error situations and/or bad user input
- Raw input numbers must be converted from strings

```
>>> name = raw input('Enter:')
Enter: Chuck
>>> print name
Chuck
>>> apple = raw input('Enter:')
Enter: 100
>>> x = apple - 10
Traceback (most recent call
last): File "<stdin>", line 1,
in <module>TypeError:
unsupported operand type(s) for
-: 'str' and 'int'
>>> x = int(apple) - 10
>>> print x
90
```

Looking Inside Strings

- We can get at any single character in a string using an index specified in square brackets
- The index value must be an integer and starts at zero

The index value can be an expression that is computed

```
b a n a n a
O 1 2 3 4 5
```

```
>>> fruit = 'banana'
>>> letter = fruit[1]
>>> print letter
a
>>> x = 3
>>> w = fruit[x - 1]
>>> print w
```

A Character Too Far

- You will get a python error if you attempt to index beyond the end of a string.
- So be careful when constructing index values and slices

```
>>> zot = 'abc'
>>> print zot[5]
Traceback (most recent call
last): File "<stdin>", line
1, in <module>IndexError:
string index out of range
>>>>
```

Strings Have Length

 There is a built-in function len that gives us the length of a string

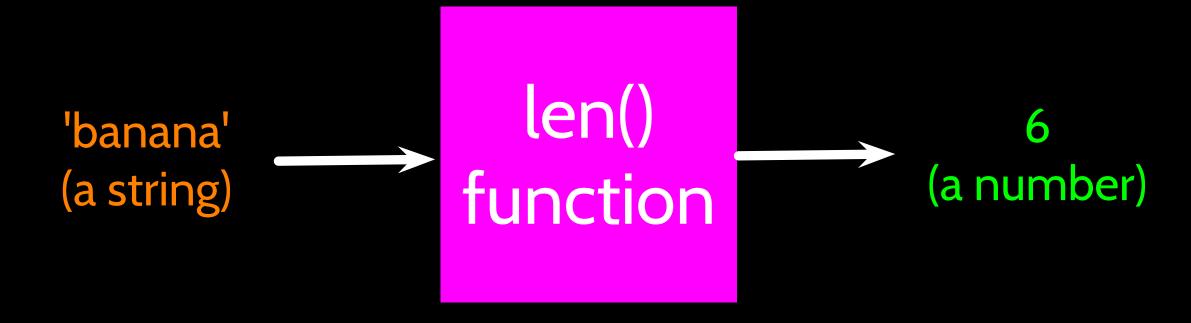

```
b a n a n a
O 1 2 3 4 5
```

```
>>> fruit = 'banana'
>>> print len(fruit)
6
```

Len Function

```
>>> fruit = 'banana'
>>> x = len(fruit)
>>> print x
6
```

A function is some stored code that we use. A function takes some input and produces an output.

Guido wrote this code

Looping Through Strings

 Using a while statement and an iteration variable, and the len function, we can construct a loop to look at each of the letters in a string individually

```
fruit = 'banana'
index = 0
while index < len(fruit):
   letter = fruit[index]
   print index, letter
   index = index + 1</pre>
0 b
1a
2n
4n
5a
```

Looping Through Strings

 A definite loop using a for statement is much more elegant

 The iteration variable is completely taken care of by the for loop

```
fruit = 'banana'
for letter in fruit:
    print letter
```

b

a

n

a

n

a

Looping Through Strings

fruit = 'banana'

 A definite loop using a for statement is much more elegant

 The iteration variable is completely taken care of by the for loop

```
for letter in fruit :
    print letter

index = 0
while index < len(fruit) :
    letter = fruit[index]
    print letter</pre>
```

index = index + 1

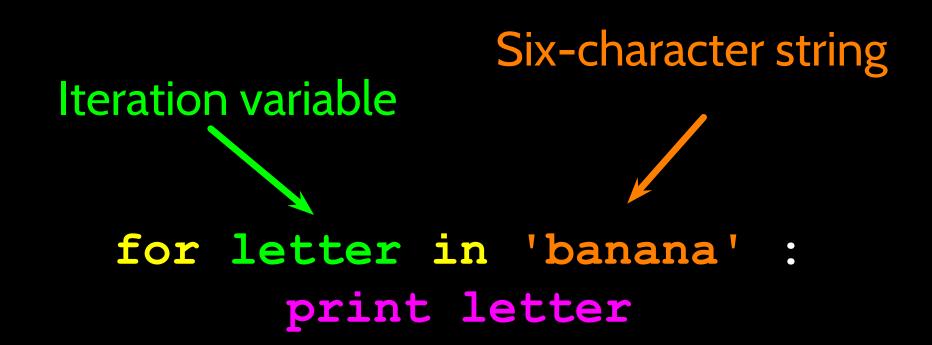

Looping and Counting

 This is a simple loop that loops through each letter in a string and counts the number of times the loop encounters the 'a' character

```
word = 'banana'
count = 0
for letter in word :
    if letter == 'a' :
        count = count + 1
print count
```

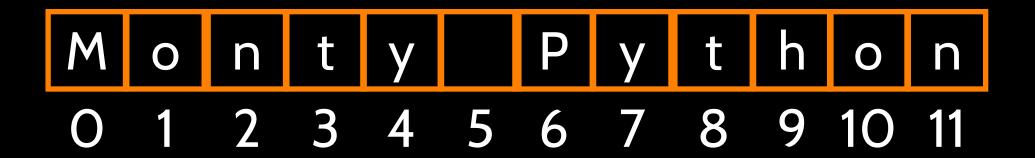

Looking deeper into in

- The iteration variable "iterates" through the sequence (ordered set)
- The block (body) of code is executed once for each value in the sequence
- The iteration variable moves through all of the values in the sequence

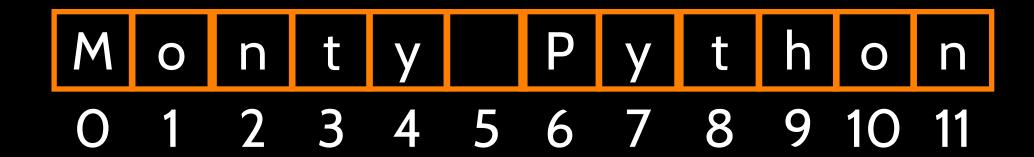

The iteration variable "iterates" through the string and the block (body) of code is executed once for each value in the sequence

- We can also look at any continuous section of a string using a colon operator
- The second number is one beyond the end of the slice -"up to but not including"
- If the second number is beyond the end of the string, it stops at the end

```
>>> s = 'Monty Python'
>>> print s[0:4]
Mont
>>> print s[6:7]
P
>>> print s[6:20]
Python
```

Slicing Strings

• If we leave off the first number or the last number of the slice, it is assumed to be the beginning or end of the string respectively

```
>>> s = 'Monty Python'
>>> print s[:2]
Mo
>>> print s[8:]
thon
>>> print s[:]
Monty Python
```

Slicing Strings

String Concatenation

 When the + operator is applied to strings, it means "concatenation"

```
>>> a = 'Hello'
>>> b = a + 'There'
>>> print b
HelloThere
>>> c = a + ' ' + 'There'
>>> print c
Hello There
>>>
```

Using in as a logical Operator

- The in keyword can also be used to check to see if one string is "in" another string
- The in expression is a logical expression that returns True or False and can be used in an if statement

```
>>> fruit = 'banana'
>>> 'n' in fruit
True
>>> 'm' in fruit
False
>>> 'nan' in fruit
True
>>> if 'a' in fruit :
        print 'Found it!'
Found it!
>>>
```

String Comparison

```
if word == 'banana':
    print 'All right, bananas.'

if word < 'banana':
    print 'Your word,' + word + ', comes before banana.'
elif word > 'banana':
    print 'Your word,' + word + ', comes after banana.'
else:
    print 'All right, bananas.'
```

String Library

- Python has a number of string functions which are in the string library
- These functions are already built into every string - we invoke them by appending the function to the string variable
- These functions do not modify the original string, instead they return a new string that has been altered

```
>>> greet = 'Hello Bob'
>>> zap = greet.lower()
>>> print zap
hello bob
>>> print greet
Hello Bob
>>> print 'Hi There'.lower()
hi there
>>>
```

```
>>> stuff = 'Hello world'
>>> type(stuff)
<type 'str'>
>>> dir(stuff)
['capitalize', 'center', 'count', 'decode', 'encode',
'endswith', 'expandtabs', 'find', 'format', 'index',
'isalnum', 'isalpha', 'isdigit', 'islower', 'isspace',
'istitle', 'isupper', 'join', 'ljust', 'lower',
'lstrip', 'partition', 'replace', 'rfind', 'rindex',
'rjust', 'rpartition', 'rsplit', 'rstrip', 'split',
'splitlines', 'startswith', 'strip', 'swapcase',
'title', 'translate', 'upper', 'zfill']
```

https://docs.python.org/2/library/stdtypes.html#string-methods

str. replace(old, new[, count])

Return a copy of the string with all occurrences of substring old replaced by new. If the optional argument count is given, only the first count occurrences are replaced.

str. rfind(sub[, start[, end]])

Return the highest index in the string where substring *sub* is found, such that *sub* is contained within s[start,end]. Optional arguments *start* and *end* are interpreted as in slice notation. Return on failure.

str. rindex(sub[, start[, end]])

Like rfind() but raises valueError when the substring sub is not found.

str.rjust(width[, fillchar])

Return the string right justified in a string of length width. Padding is done using the specified fillchar (default is a space). The original string is returned if width is less than len(s).

String Library

```
str.capitalize()str.replace(old, new[, count])str.center(width[, fillchar])str.lower()str.endswith(suffix[, start[, end]])str.rstrip([chars])str.find(sub[, start[, end]])str.strip([chars])str.lstrip([chars])str.upper()
```

Searching a String

- We use the find() function to search for a substring within another string
- find() finds the first occurrence of the substring
- If the substring is not found, find() returns -1
- Remember that string position starts at zero

```
b a n a n a
O 1 2 3 4 5
```

```
>>> fruit = 'banana'
>>> pos = fruit.find('na')
>>> print pos
2
>>> aa = fruit.find('z')
>>> print aa
-1
```

Making everything UPPER CASE

- You can make a copy of a string in lower case or upper case
- Often when we are searching for a string using find() - we first convert the string to lower case so we can search a string regardless of case

```
>>> greet = 'Hello Bob'
>>> nnn = greet.upper()
>>> print nnn
HELLO BOB
>>> www = greet.lower()
>>> print www
hello bob
>>>
```

Search and Replace

The replace()
 function is like a
 "search and replace"
 operation in a word
 processor

It replaces all
 occurrences of the
 search string with the
 replacement string

```
>>> greet = 'Hello Bob'
>>> nstr = greet.replace('Bob','Jane')
>>> print nstr
Hello Jane
>>> nstr = greet.replace('o','X')
>>> print nstr
HellX BXb
>>>
```

Stripping Whitespace

- Sometimes we want to take a string and remove whitespace at the beginning and/or end
- lstrip() and rstrip() remove
 whitespace at the left or right
- strip() removes both beginning and ending whitespace

```
>>> greet = ' Hello Bob'
>>> greet.lstrip()
'Hello Bob '
>>> greet.rstrip()
' Hello Bob'
>>> greet.strip()
'Hello Bob'
>>>
```

Prefixes

```
>>> line = 'Please have a nice day'
>>> line.startswith('Please')
True
>>> line.startswith('p')
False
```

Parsing and Extracting

```
From stephen.marquard@uct.ac.za Sat Jan 5 09:14:16 2008
>>> data = 'From stephen.marquard@uct.ac.za Sat Jan 5 09:14:16 2008'
>>> atpos = data.find('@')
>>> print atpos
21
>>> sppos = data.find(' ',atpos)
>>> print sppos
31
>>> host = data[atpos+1 : sppos]
>>> print host
```

uct.ac.za

Summary

- String type
- Read/Convert
- Indexing strings
- Slicing strings [2:4]
- Looping through strings with for and while
- Concatenating strings with +

- String operations
- String library
- String Comparisons
- Searching in strings
- Replacing text
- Stripping white space
